

Python Data Structures Cheat Sheet

List

Package/ Method	Description	Code Example
append()	The `append()` method is used to add an element to the end of a list.	<div>Syntax:</div> <div><div>1</div><div>list_name.append(element)</div><div></div></div> <div>Example:</div> <div><div>1</div><div>fruits = ["apple", "banana", "orange"]</div><div>2</div><div>fruits.append("mango") print(fruits)</div><div></div></div>
copy()	The `copy()` method is used to create a shallow copy of a list.	<div>Example 1:</div> <div><div>1</div><div>my_list = [1, 2, 3, 4, 5]</div><div>2</div><div>new_list = my_list.copy() print(new_list)</div><div>3</div><div># Output: [1, 2, 3, 4, 5]</div><div></div></div>
count()	The `count()` method is used to count the number of occurrences of a specific element in a list in Python.	<div>Example:</div> <div><div>1</div><div>my_list = [1, 2, 2, 3, 4, 2, 5, 2]</div><div>2</div><div>count = my_list.count(2) print(count)</div><div>3</div><div># Output: 4</div><div></div></div>
Creating a list	A list is a built-in data type that represents an ordered and mutable collection of elements. Lists are enclosed in square brackets [] and elements are separated by commas.	<div>Example:</div> <div><div>1</div><div>fruits = ["apple", "banana", "orange", "mango"]</div><div></div></div>
del	The `del` statement is used to remove an element from list. `del` statement removes the element at the specified index.	<div>Example:</div> <div><div>1</div><div>my_list = [10, 20, 30, 40, 50]</div><div>2</div><div>del my_list[2] # Removes the element at index 2 print(my_list)</div><div>3</div><div># Output: [10, 20, 40, 50]</div><div></div></div>
extend()	The `extend()` method is used to add multiple elements to a list. It takes an iterable (such as another list, tuple, or string) and appends each element of the iterable to the original list.	<div>Syntax:</div> <div><div>1</div><div>list_name.extend(iterable)</div><div></div></div> <div>Example:</div> <div><div>1</div><div>fruits = ["apple", "banana", "orange"]</div><div>2</div><div>more_fruits = ["mango", "grape"]</div><div>3</div><div>fruits.extend(more_fruits)</div><div>4</div><div>print(fruits)</div><div></div></div>
Indexing	Indexing in a list allows you to access individual elements by their position. In Python, indexing starts from 0 for the first element and goes up to `length_of_list - 1`.	<div>Example:</div> <div><div>1</div><div>my_list = [10, 20, 30, 40, 50]</div><div>2</div><div>print(my_list[0])</div><div>3</div><div># Output: 10 (accessing the first element)</div><div>4</div><div>print(my_list[-1])</div><div>5</div><div># Output: 50 (accessing the last element using negative indexing)</div><div></div></div>
insert()	The `insert()` method is used to insert an element.	<div>Syntax:</div> <div><div>1</div><div>list_name.insert(index, element)</div><div></div></div> <div>Example:</div> <div><div>1</div><div>my_list = [1, 2, 3, 4, 5]</div><div>2</div><div>my_list.insert(2, 6)</div><div>3</div><div>print(my_list)</div><div></div></div>
Modifying a list	You can use indexing to modify or assign new values to specific elements in the list.	<div>Example:</div> <div><div>1</div><div>my_list = [10, 20, 30, 40, 50]</div><div>2</div><div>my_list[1] = 25 # Modifying the second element</div><div>3</div><div>print(my_list)</div><div>4</div><div># Output: [10, 25, 30, 40, 50]</div><div></div></div>
pop()	`pop()` method is another way to remove an element from a list in Python. It removes and returns the element at the specified index. If you don't provide an index to the `pop()` method, it will remove and return the last element of the list by default	<div>Example 1:</div> <div><div>1</div><div>my_list = [10, 20, 30, 40, 50]</div><div>2</div><div>removed_element = my_list.pop(2) # Removes and returns the element at index 2</div><div>3</div><div>print(removed_element)</div><div>4</div><div># Output: 30</div><div>5</div><div></div><div>6</div><div>print(my_list)</div><div>7</div><div># Output: [10, 20, 40, 50]</div><div></div></div> <div>Example 2:</div> <div><div>1</div><div>my_list = [10, 20, 30, 40, 50]</div><div>2</div><div>removed_element = my_list.pop() # Removes and returns the last element</div><div>3</div><div>print(removed_element)</div><div>4</div><div># Output: 50</div><div>5</div><div></div><div>6</div><div>print(my_list)</div><div>7</div><div># Output: [10, 20, 30, 40]</div><div></div></div>
remove()	To remove an element from a list. The `remove()` method removes the first occurrence of the specified value.	<div>Example:</div> <div><div>1</div><div>my_list = [10, 20, 30, 40, 50]</div><div>2</div><div>my_list.remove(30) # Removes the element 30</div><div>3</div><div>print(my_list)</div><div>4</div><div># Output: [10, 20, 40, 50]</div><div></div></div>
reverse()	The `reverse()` method is used to reverse the order of elements in a list	<div>Example 1:</div> <div><div>1</div><div>my_list = [1, 2, 3, 4, 5]</div><div>2</div><div>my_list.reverse() print(my_list)</div><div>3</div><div># Output: [5, 4, 3, 2, 1]</div><div></div></div>
Slicing	You can use slicing to access a range of elements from a list.	<div>Syntax:</div> <div><div>1</div><div>list_name[start:end:step]</div><div></div></div> <div>Example:</div> <div><div>1</div><div>my_list = [1, 2, 3, 4, 5]</div><div>2</div><div>print(my_list[1:4])</div><div>3</div><div># Output: [2, 3, 4] (elements from index 1 to 3)</div><div>4</div><div></div><div>5</div><div>print(my_list[:3])</div><div>6</div><div># Output: [1, 2, 3] (elements from the beginning up to index 2)</div><div>7</div><div></div><div>8</div><div>print(my_list[2:])</div><div>9</div><div># Output: [3, 4, 5] (elements from index 2 to the end)</div><div>10</div><div></div><div>11</div><div>print(my_list[::-2])</div><div>12</div><div># Output: [1, 3, 5] (every second element)</div><div></div></div>
sort()	The `sort()` method is used to sort the elements of a list in ascending order. If you want to sort the list in descending order, you can pass the `reverse=True` argument to the `sort()` method.	<div>Example 1:</div> <div><div>1</div><div>my_list = [5, 2, 8, 1, 9]</div><div>2</div><div>my_list.sort()</div><div>3</div><div>print(my_list)</div><div>4</div><div># Output: [1, 2, 5, 8, 9]</div><div></div></div> <div>Example 2:</div> <div><div>1</div><div>my_list = [5, 2, 8, 1, 9]</div><div>2</div><div>my_list.sort(reverse=True)</div><div>3</div><div>print(my_list)</div><div>4</div><div># Output: [9, 8, 5, 2, 1]</div><div></div></div>

Tuple

Package/ Method	Description	Code Example
count()	The count() method for a tuple is used to count how many times a specified element appears in the tuple.	<div>Syntax:</div> <div><div>1</div><div>tuple.count(value)</div><div></div></div> <div>Example:</div> <div><div>1</div><div>fruits = ("apple", "banana", "apple", "orange")</div><div>2</div><div>print(fruits.count("apple")) #Counts the number of times apple is found in tupl^.</div><div>3</div><div>#Output: 2</div><div></div></div>
index()	The index() method in a tuple is used to find the first occurrence of a specified value and returns its position (index). If the value is not found, it raises a ValueError.	<div>Syntax:</div> <div><div>1</div><div>tuple.index(value)</div><div></div></div> <div>Example:</div> <div><div>1</div><div>fruits = ("apple", "banana", "orange")</div><div>2</div><div>print(fruits[1]) #Returns the value at which apple is present.</div><div>3</div><div>#Output: banana</div><div></div></div>
sum()	The sum() function in Python can be used to calculate the sum of all elements in a tuple, provided that the elements are numeric (integers or floats).	<div>Syntax:</div> <div><div>1</div><div>sum(tuple)</div><div></div></div> <div>Example:</div> <div><div>1</div><div>numbers = (10, 20, 5, 30)</div><div>2</div><div>print(sum(numbers))</div><div>3</div><div>#Output: 65</div><div></div></div>
min() and max()	Find the smallest (min()) or largest (max()) element in a tuple.	<div>Example:</div> <div><div>1</div><div>numbers = (10, 20, 5, 30)</div><div>2</div><div>print(min(numbers))</div><div>3</div><div>#Output: 5</div><div>4</div><div>print(max(numbers))</div><div>5</div><div>#Output: 30</div><div></div></div>
len()	Get the number of elements in the tuple using len().	<div>Syntax:</div> <div><div>1</div><div>len(tuple)</div><div></div></div> <div>Example:</div> <div><div>1</div><div>fruits = ("apple", "banana", "orange")</div><div>2</div><div>print(len(fruits)) #Returns length of the tuple.</div><div>3</div><div>#Output: 3</div><div></div></div>
